## Introduction

*Staphylococcus lugdunensis* (SLU) is an emergent virulent coagulase-negative *Staphylococcus* that is increasingly responsible for severe infections resembling those caused by *S. aureus*, such as skin and soft tissue infections, infective endocarditis and bone and joint infections.

In an attempt to generate informative sequence data for subtyping SLU, we developed both a classical length-based **MLVA** scheme and a **sequence-based MLVA scheme** (Tandem Repeat Sequence Typing, **TRST**), and assessed their performances compared to MultiLocus Sequence Typing (**MLST**)<sup>1</sup> and Multivirulence Locus Sequence Typing (**MVLST**)<sup>2</sup>.

## Methods

### MLVA and TRST assays development

- SLU genomes **N920143**<sup>3</sup> and **HKU09-01**<sup>4</sup> were screened *in silico* for the presence of tandem repeats (TRs) with Tandem Repeats Finder software (TRF).
- Selected VNTRs loci were tested on a panel of :
  - **30 genetically diverse SLU strains** representative of the main clonal groups defined by MLST (including 10 closely related isolates).
  - a collection of **98 clinical isolates** (82 pathogenic isolates from diverse clinical settings and 16 carriage isolates) collected from November 2013 to March 2016 at the University Hospital of Strasbourg in France<sup>5</sup>, to evaluate overall performances of the new methods.
- **Number and sequences** of TRs were identified for each VNTR with **BioNumerics software 7.6**, and each unique combination was converted into distinct **MLVA types (MTs)** and **TRST types (TRTs)**.

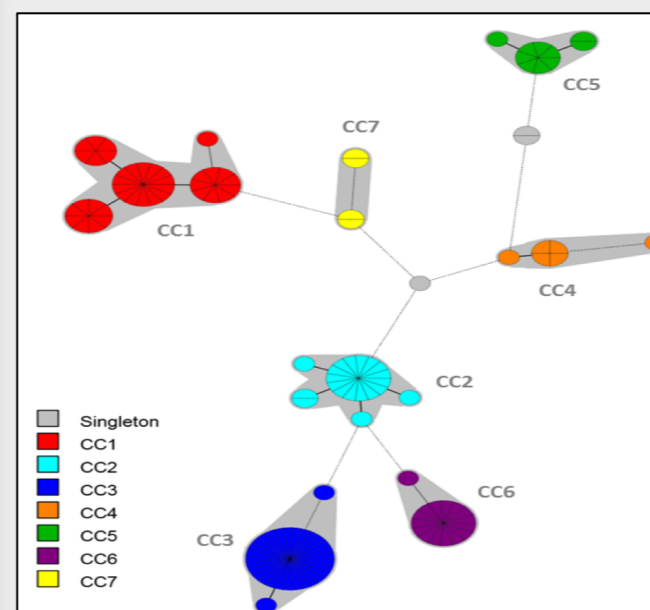

### MLST and MVLST assays

- MLST and trilocus-MVLST genotyping were performed for the **128** isolates by sequencing 7 housekeeping<sup>1</sup> and 3 virulence-associated genes<sup>2</sup>, respectively.
- Allelic profiles and corresponding **sequence types (STs)** as well as **trilocus virulence types (VT<sup>T</sup>s)** were determined with BioNumerics. STs were clustered into **clonal complexes (CCs)** with eBURST v3.

### Data analysis

- All typing data were uploaded into BioNumerics to generate **minimum spanning trees (MST)**.
- Discriminatory ability of the methods were evaluated by the **Simpson's index of diversity (DI)** and associated **confidence intervals (CI)**.

## MLST and MVLST genotyping

**Figure 1. MST of the 128 SLU isolates typed by MLST.**

The colors used are based on CCs. Each circle represents an ST and its size is proportional to the number of strains. Thick, short lines connecting two types denote types differing in a single locus; thin, longer lines connect double-locus variants; and dashed lines indicate the most likely connection between two types differing in more than two loci. Gray zones around circles delineate CCs.

### Characteristics of the 7 VNTRs loci

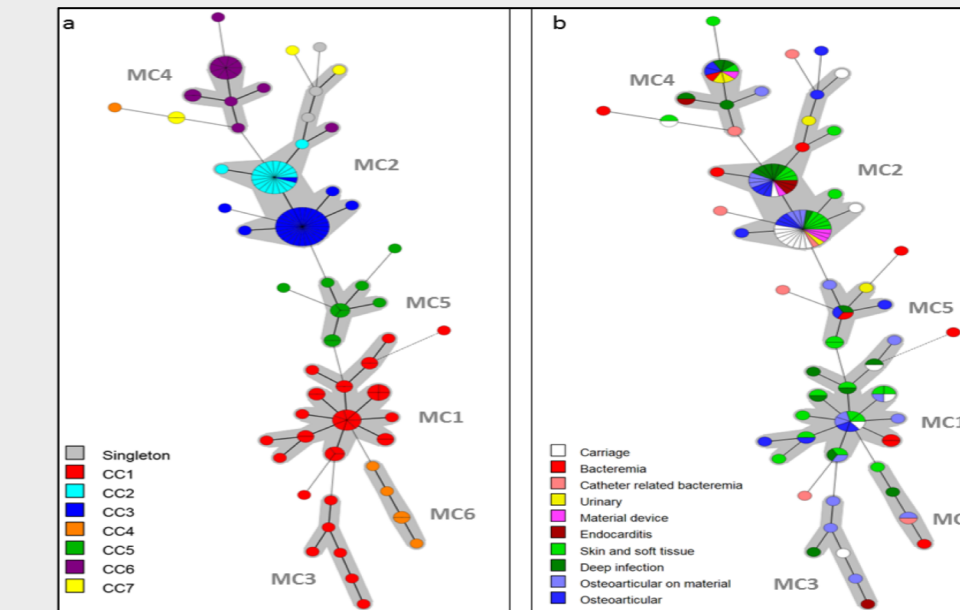

- Identification of **28** VNTRs with TRF → 7 selected: **SLU1 to SLU7**
- **Heterogeneity** of TR copy ranges and DI (**Table 1**).

VNTR name	Putative function	Repeat size (bp)	Copy no. range	MLVA scheme		TRST scheme		
				DI	CI* 95%	No. of alleles	DI	CI 95%
SLU1	Non-coding	57	1-3	0.531	0.500-0.562	6	0.656	0.609-0.702
SLU2	Hypothetical protein	58	1-4	0.595	0.523-0.667	21	0.801	0.745-0.856
SLU3	Hypothetical protein	48	3-11	0.679	0.615-0.743	27	0.889	0.859-0.918
SLU4	Non-coding	57	1-6	0.666	0.617-0.715	14	0.757	0.706-0.808
SLU5	Non-coding	57	2-5	0.479	0.393-0.566	19	0.849	0.819-0.879
SLU6	Hypothetical protein	58	1-5	0.566	0.503-0.629	18	0.850	0.819-0.880
SLU7	AraC family transcriptional regulator	24	2-3	0.090	0.022-0.158	4	0.120	0.043-0.197

**Table 1. Characteristics of the 7 VNTRs loci.**

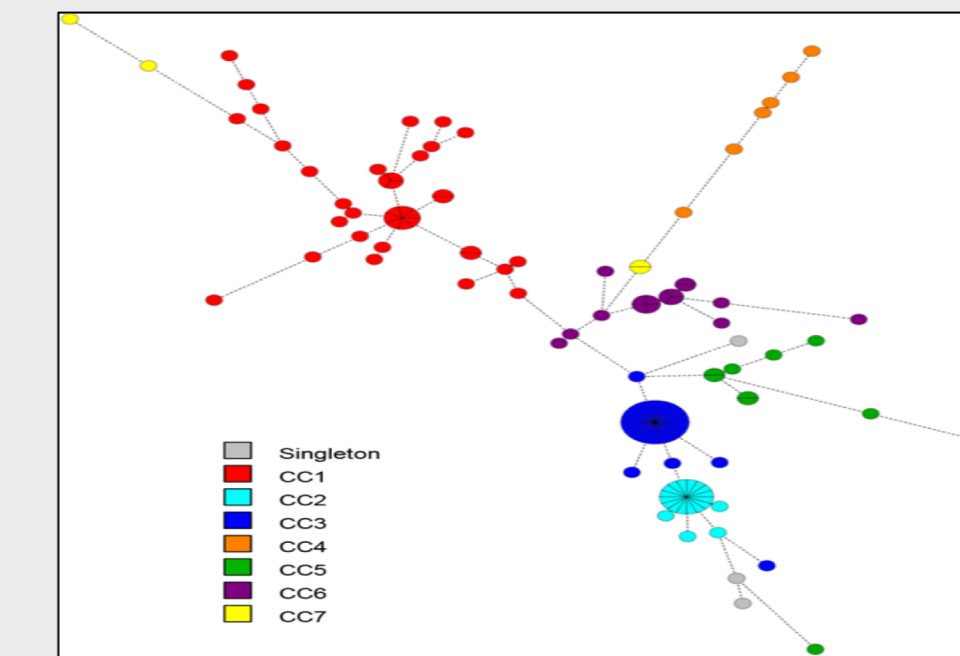

## Results

### MLVA and TRST genotyping and clustering

**Figure 2. MST of the 128 SLU isolates typed by MLVA.**

The colors used are based on (a) CCs defined by MLST and (b) clinical contexts. Each circle represents a MT and its size is proportional to the number of strains. Gray zones around circles delineate MCs.

**Figure 3. MST of the 128 SLU isolates typed by TRST.**

The colors used are based on CCs defined by MLST. Each circle represents a TRT and its size is proportional to the number of strains.

### MLVA :

- **55** MTs distributed into **6** MCs (**Figure 2a**)
- Main MCs: **MC1** (n=30) and **MC2** (n=54)
- $DI_{MLVA} = 0,933$   
→ **more discriminant than MLST/MVLST**
- No cluster specific to clinical presentation (**Figure 2b**)

### TRST :

- **69** TRTs (**Figure 3**)
- $DI_{TRST} = 0,943$   
→ **highly discriminant**

**MLVA and TRST clustering :**  
distribution similar to that obtained by MLST, with efficient subdivision of some CCs (especially the CC1)

## Conclusion

- We describe here the first **VNTRs-based schemes** for *Staphylococcus lugdunensis* subtyping.
- MLVA and TRST were **more discriminant** compared to MLST and MVLST, and the clustering achieved by the four typing methods **was highly congruent**.
- In conclusion, **MLVA and TRST represent very promising tools** to distinguish between strains of homogenous lineages in this clonal species, and provide valuable information for molecular epidemiological studies of *Staphylococcus lugdunensis*.
