Introduction

- Many organic pollutants such as PAHs and PCBs and metal contaminants are accumulated in the sediment
- Consequences:**
 - Damaging aquatic ecosystems
 - Toxic for life including human-beings
- Aims of researches:**
 - Develop extraction and analytical methods for these pollutants and their metabolites
 - Using electro-kinetic (EK) method for reducing their quantities in sediment

- Organic pollutants:
 - 16 polycyclic aromatic hydrocarbons (PAHs)
 - 2 rings: naphthalene
 - 3 rings: phenanthrene
 - ... 5 rings: benzo[a]pyrene

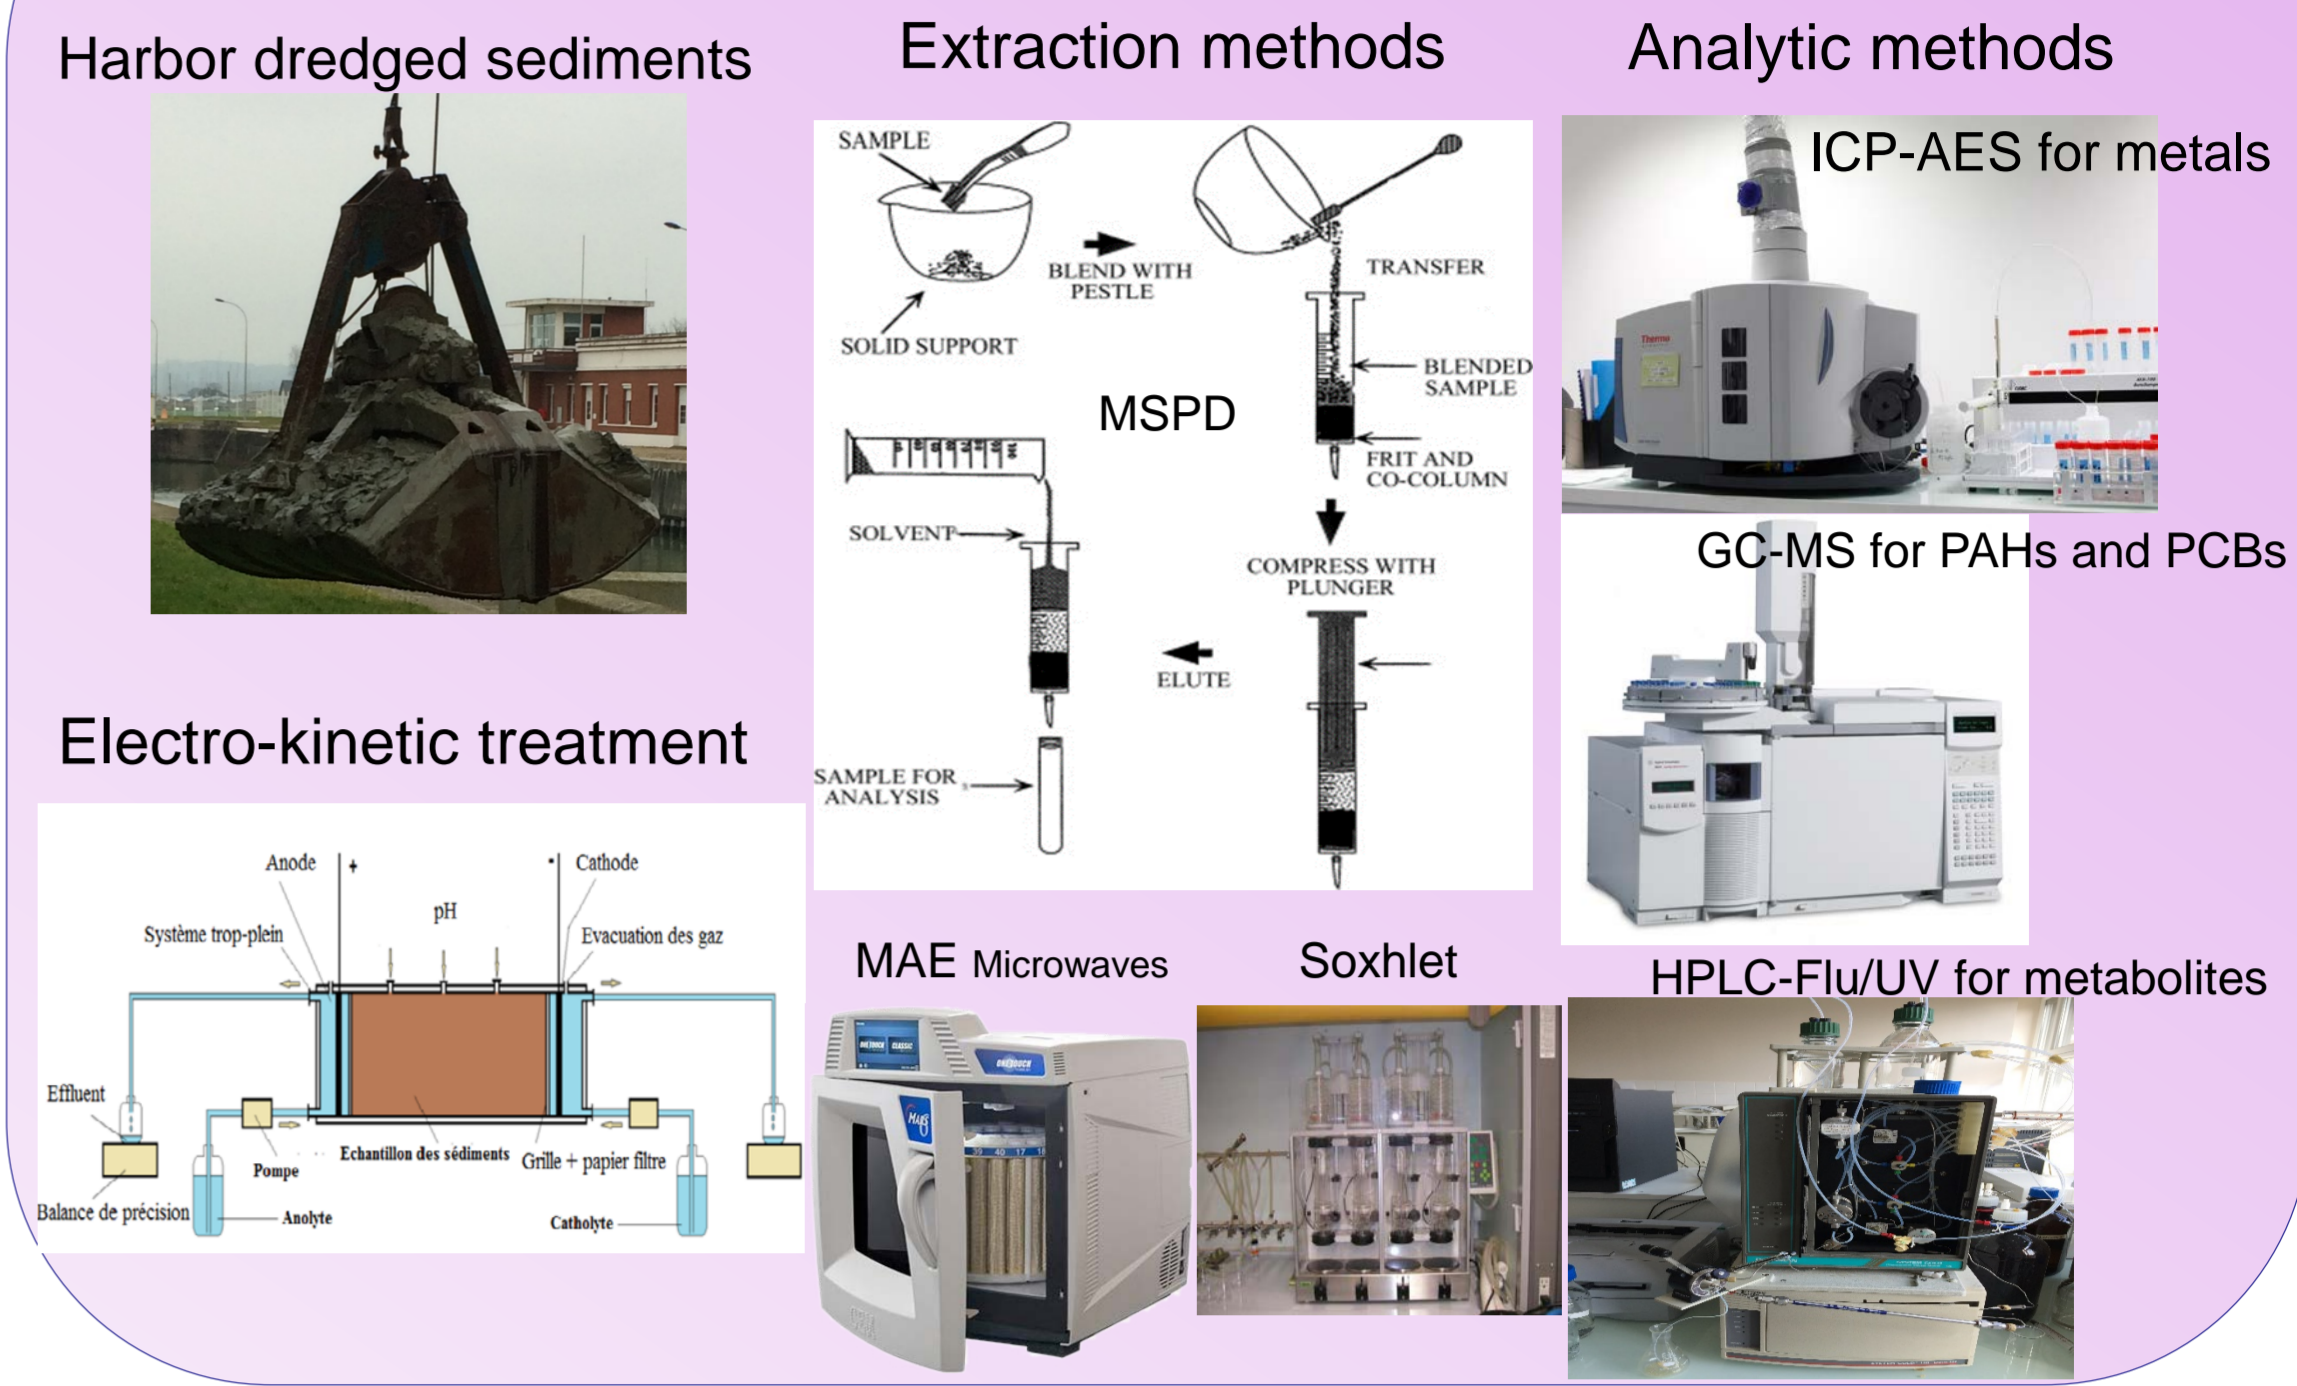

- 7 Polychlorinated biphenyls (PCBs)

- Inorganics: metal contaminants

Materials & Methods

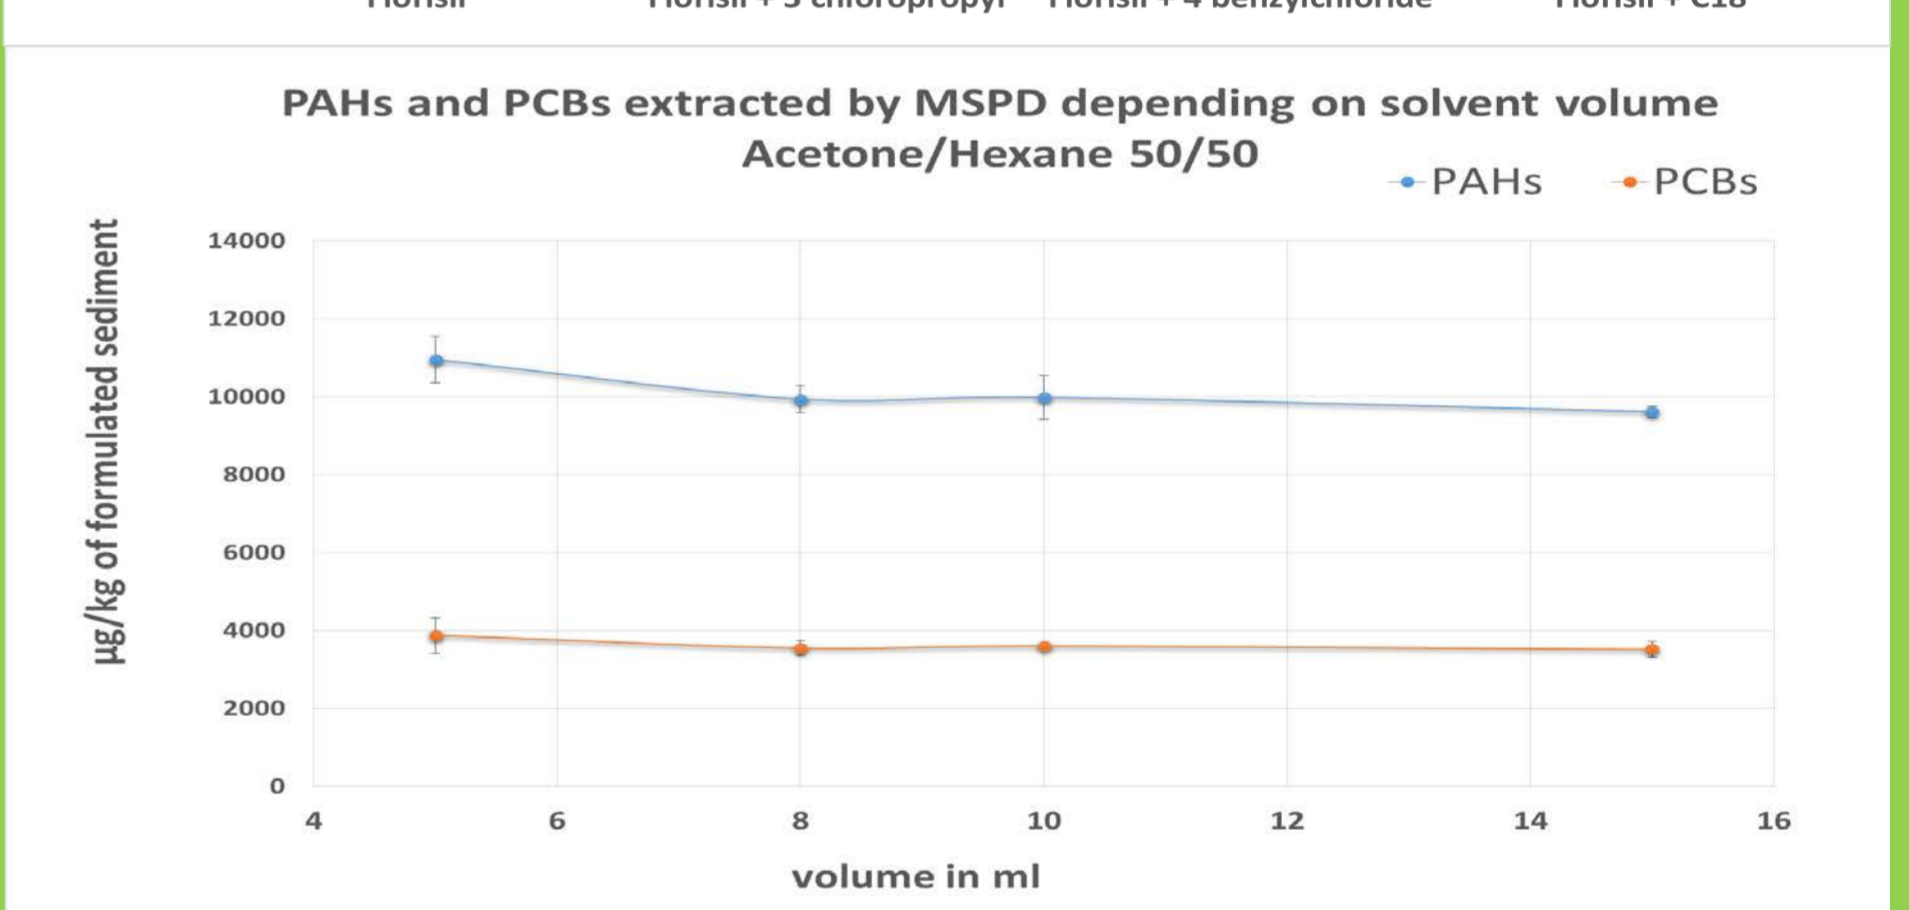

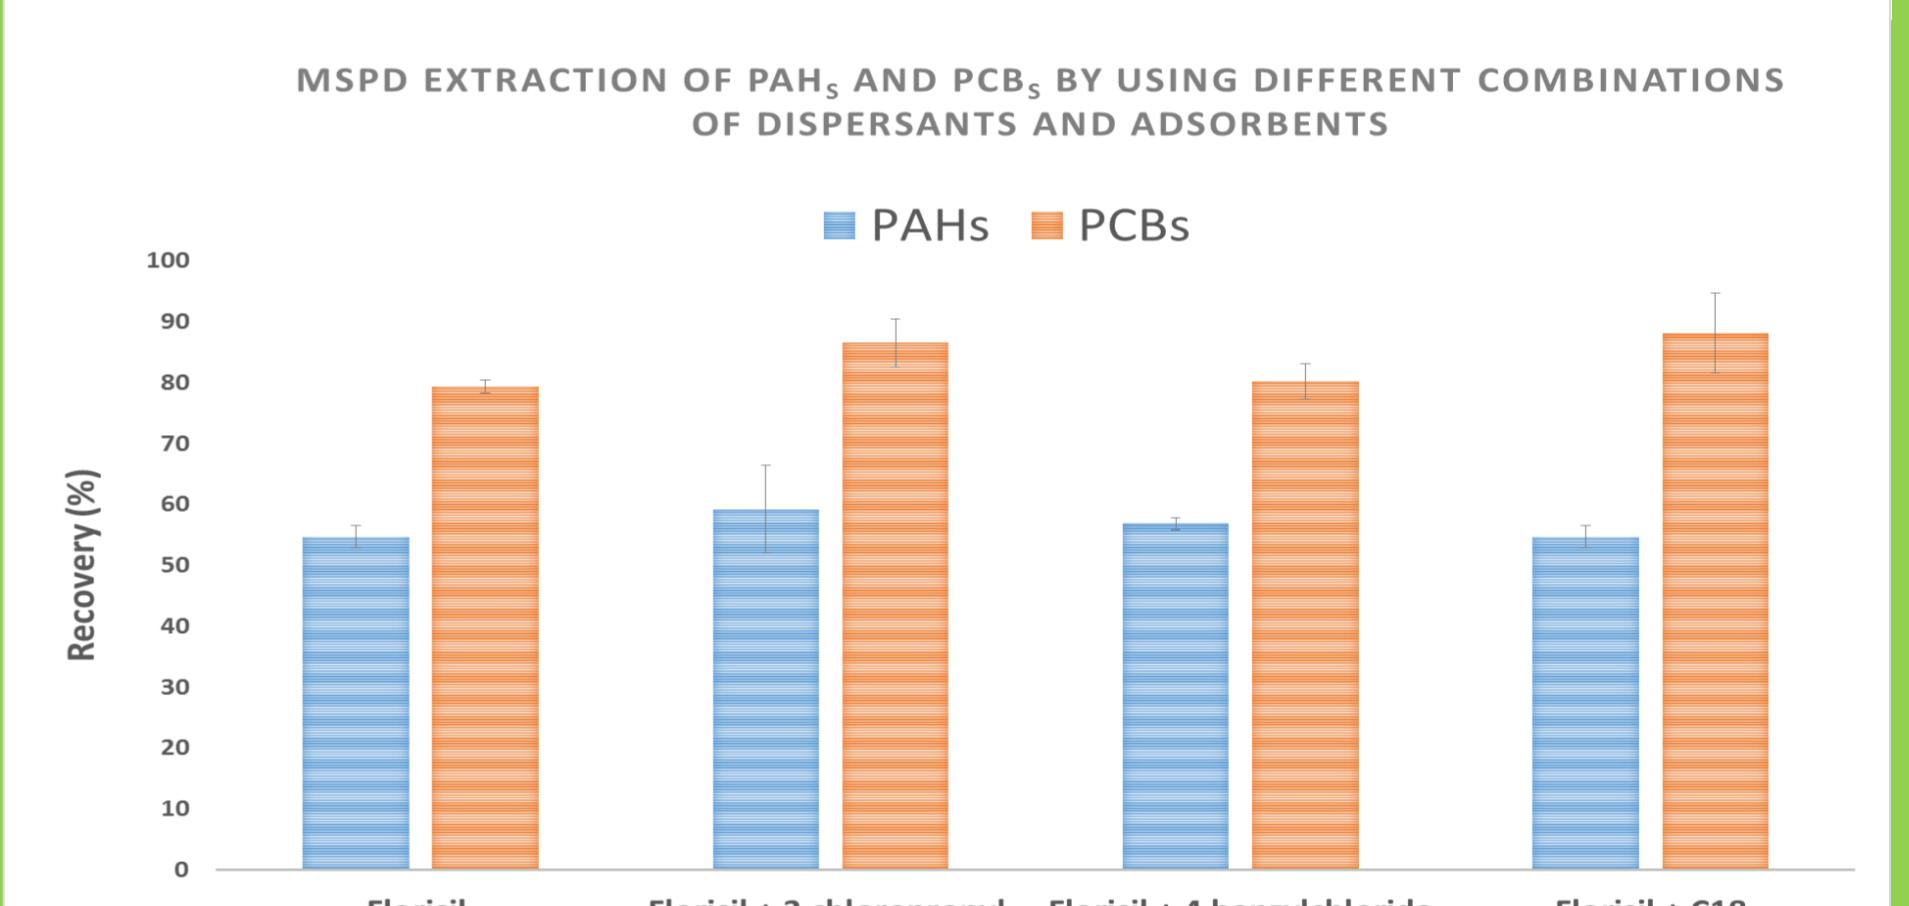

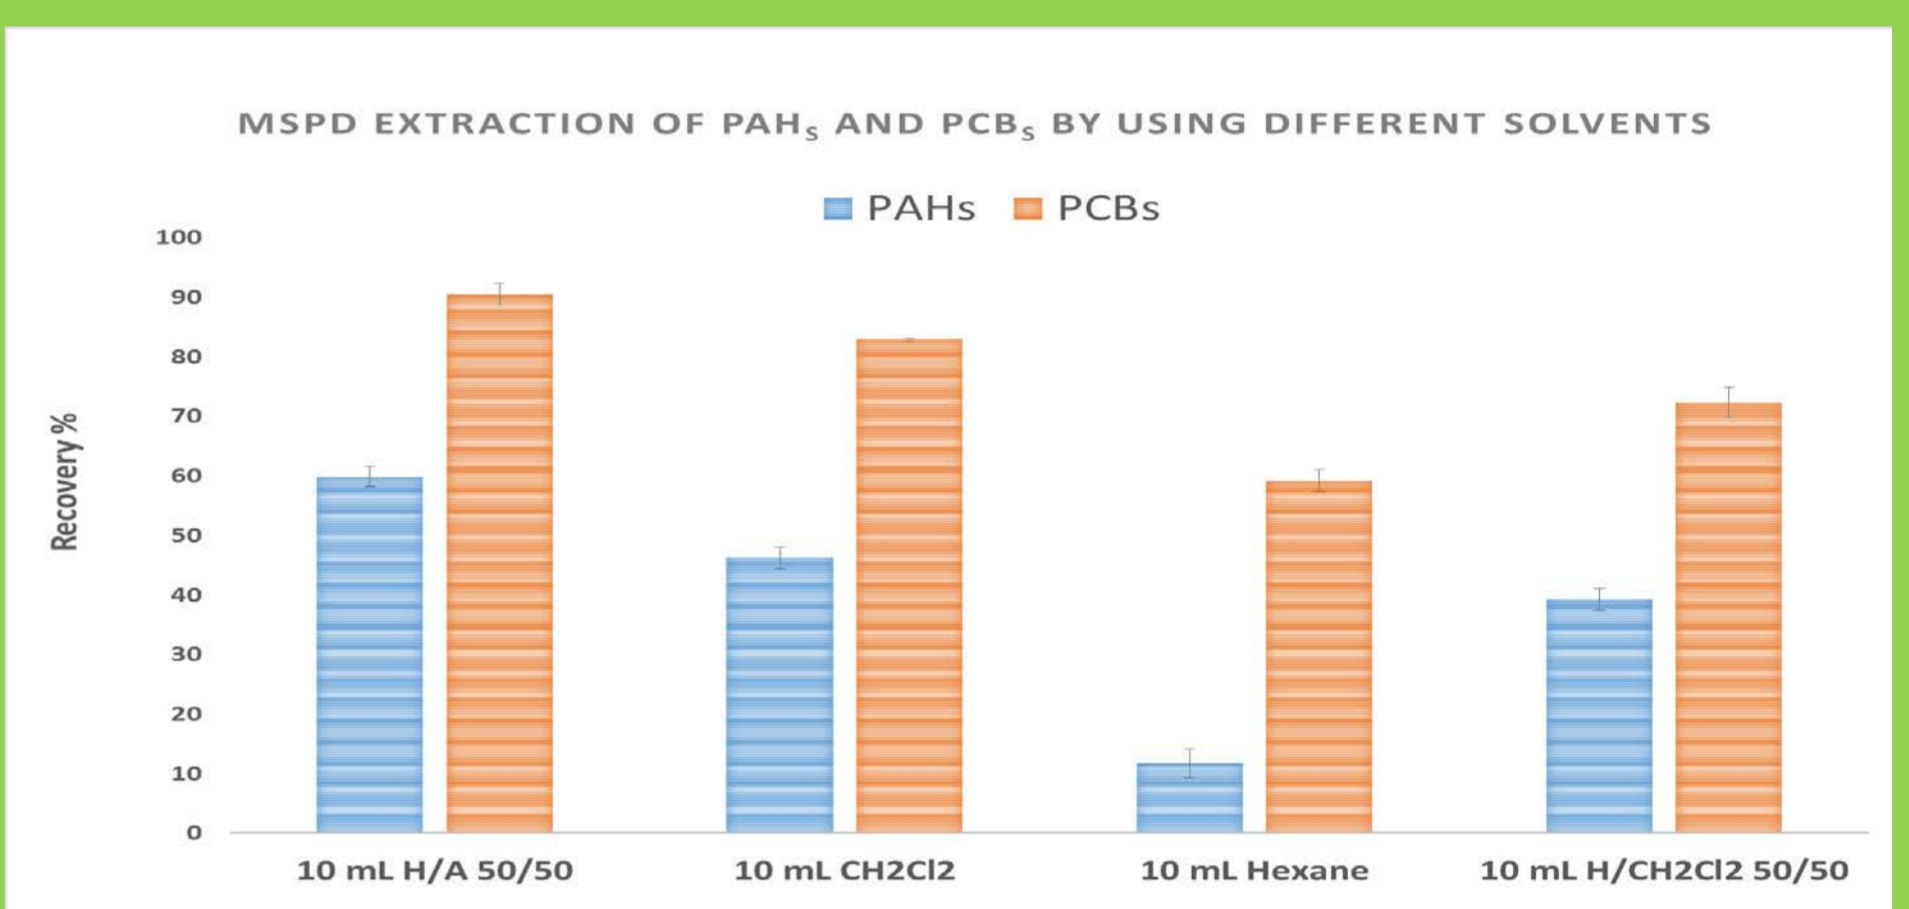

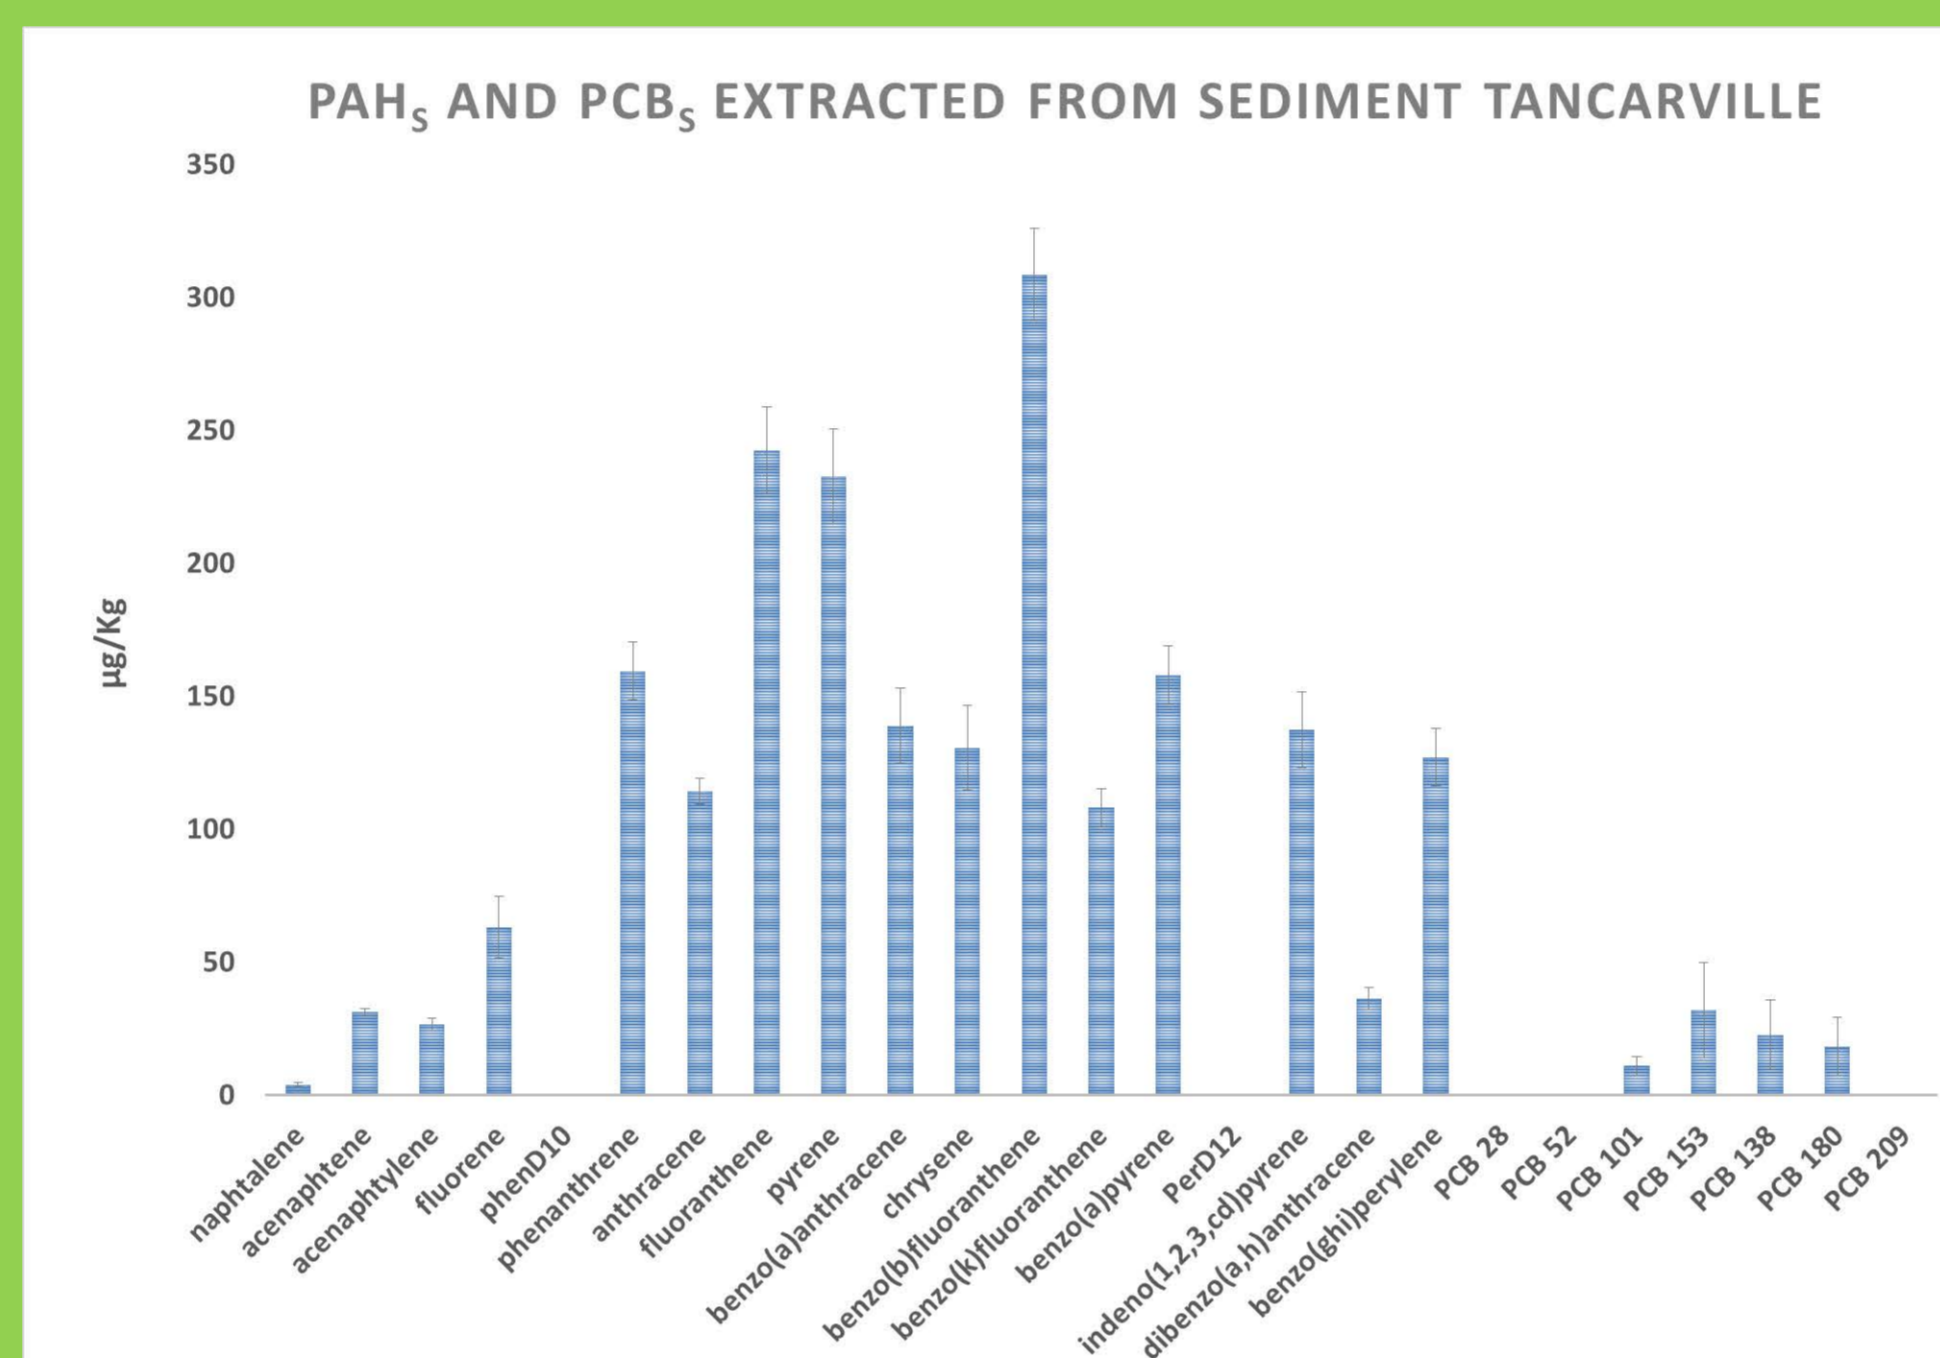

Results and discussions

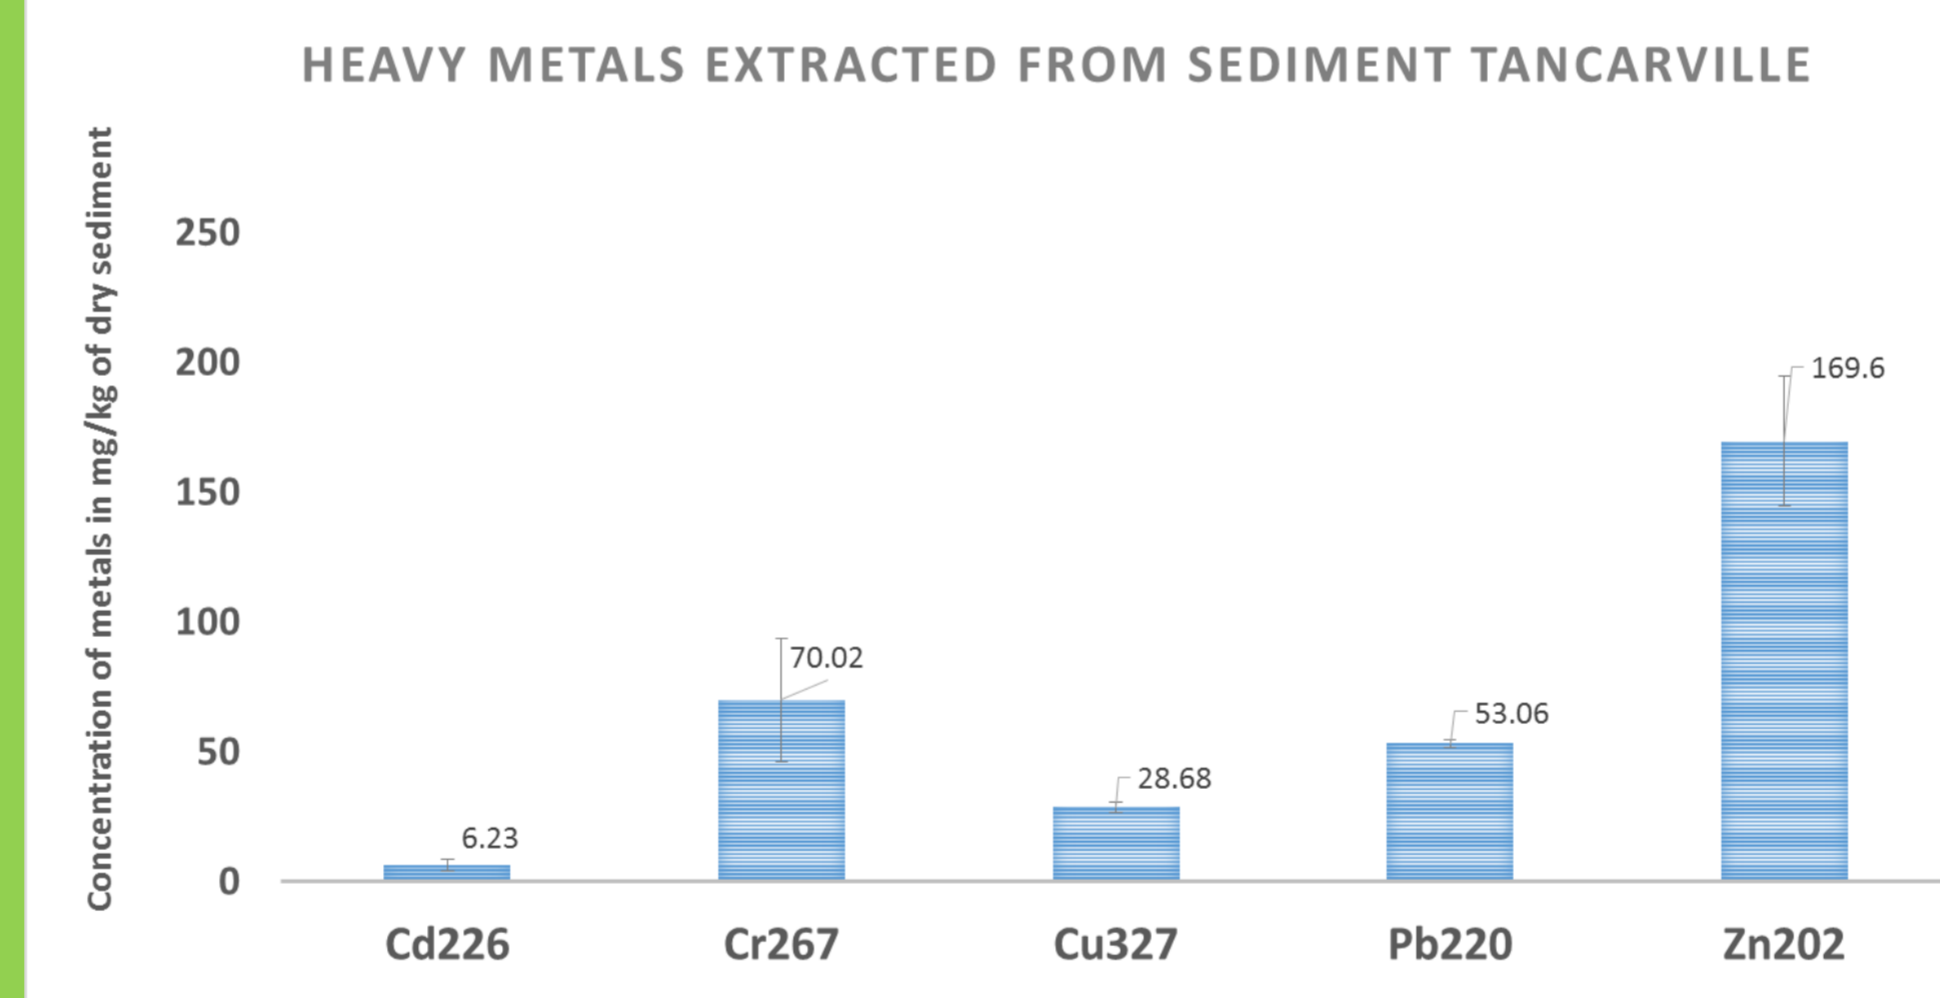

GC-MS analysis of PAHs and PCBs

Extraction of real sediment pollutants from Tancarville

MSPD: matrix solid phase dispersive extraction

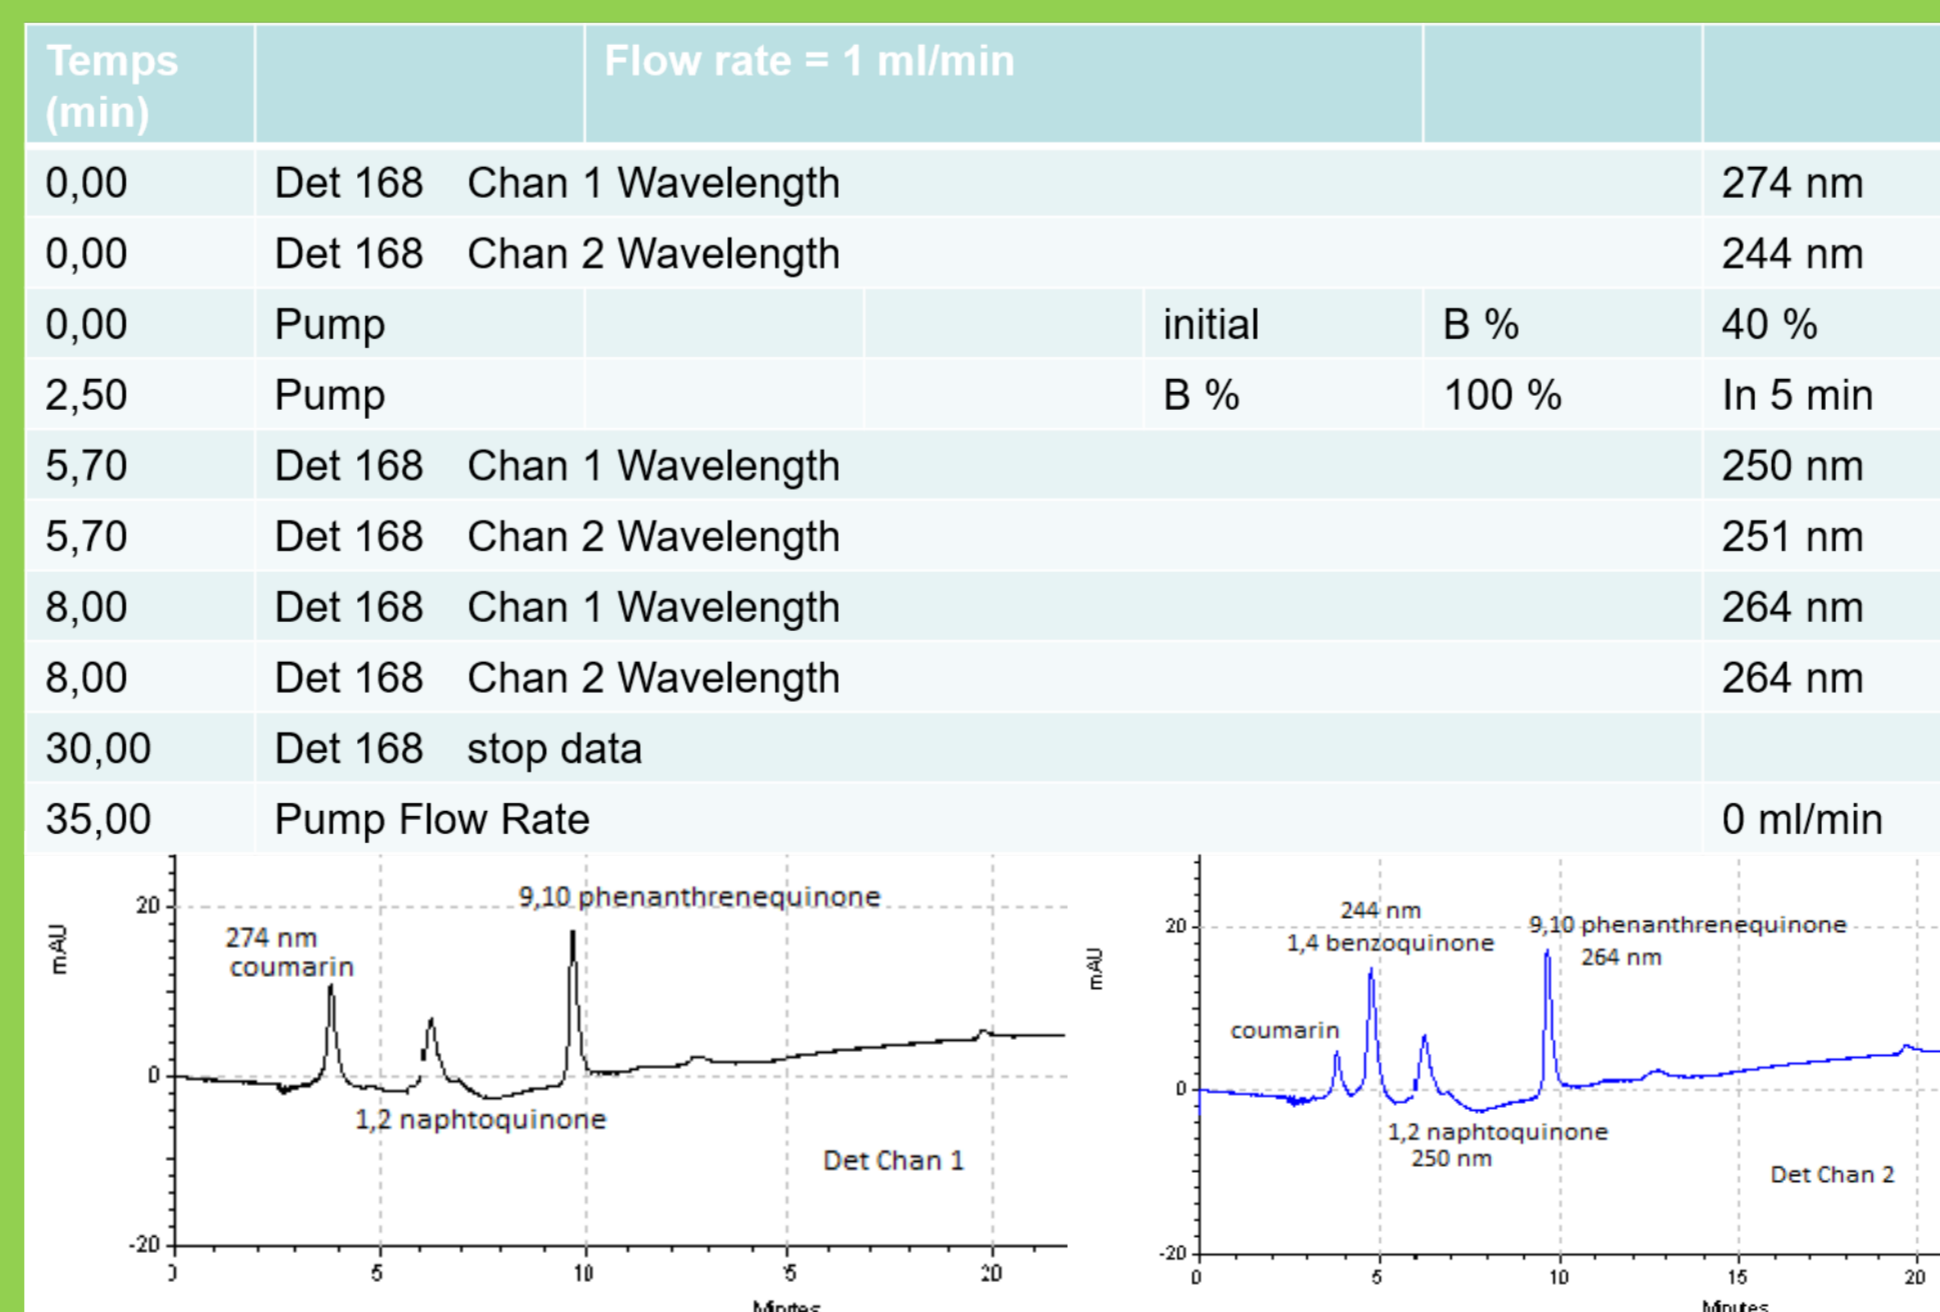

Extraction of soil organic pollutants

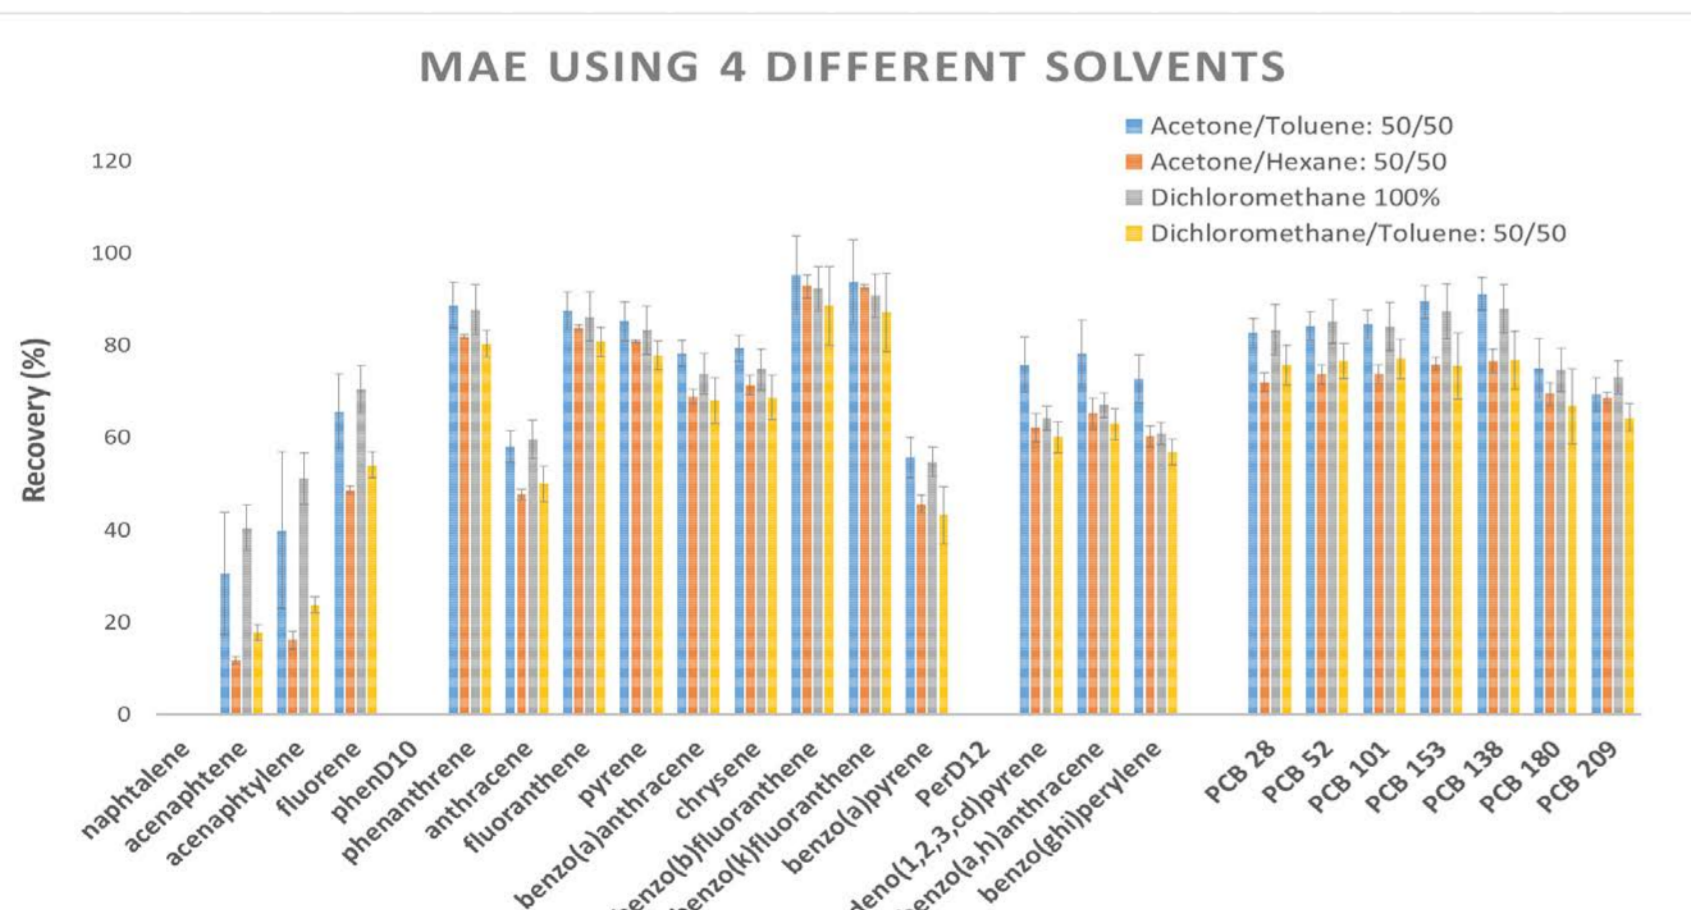

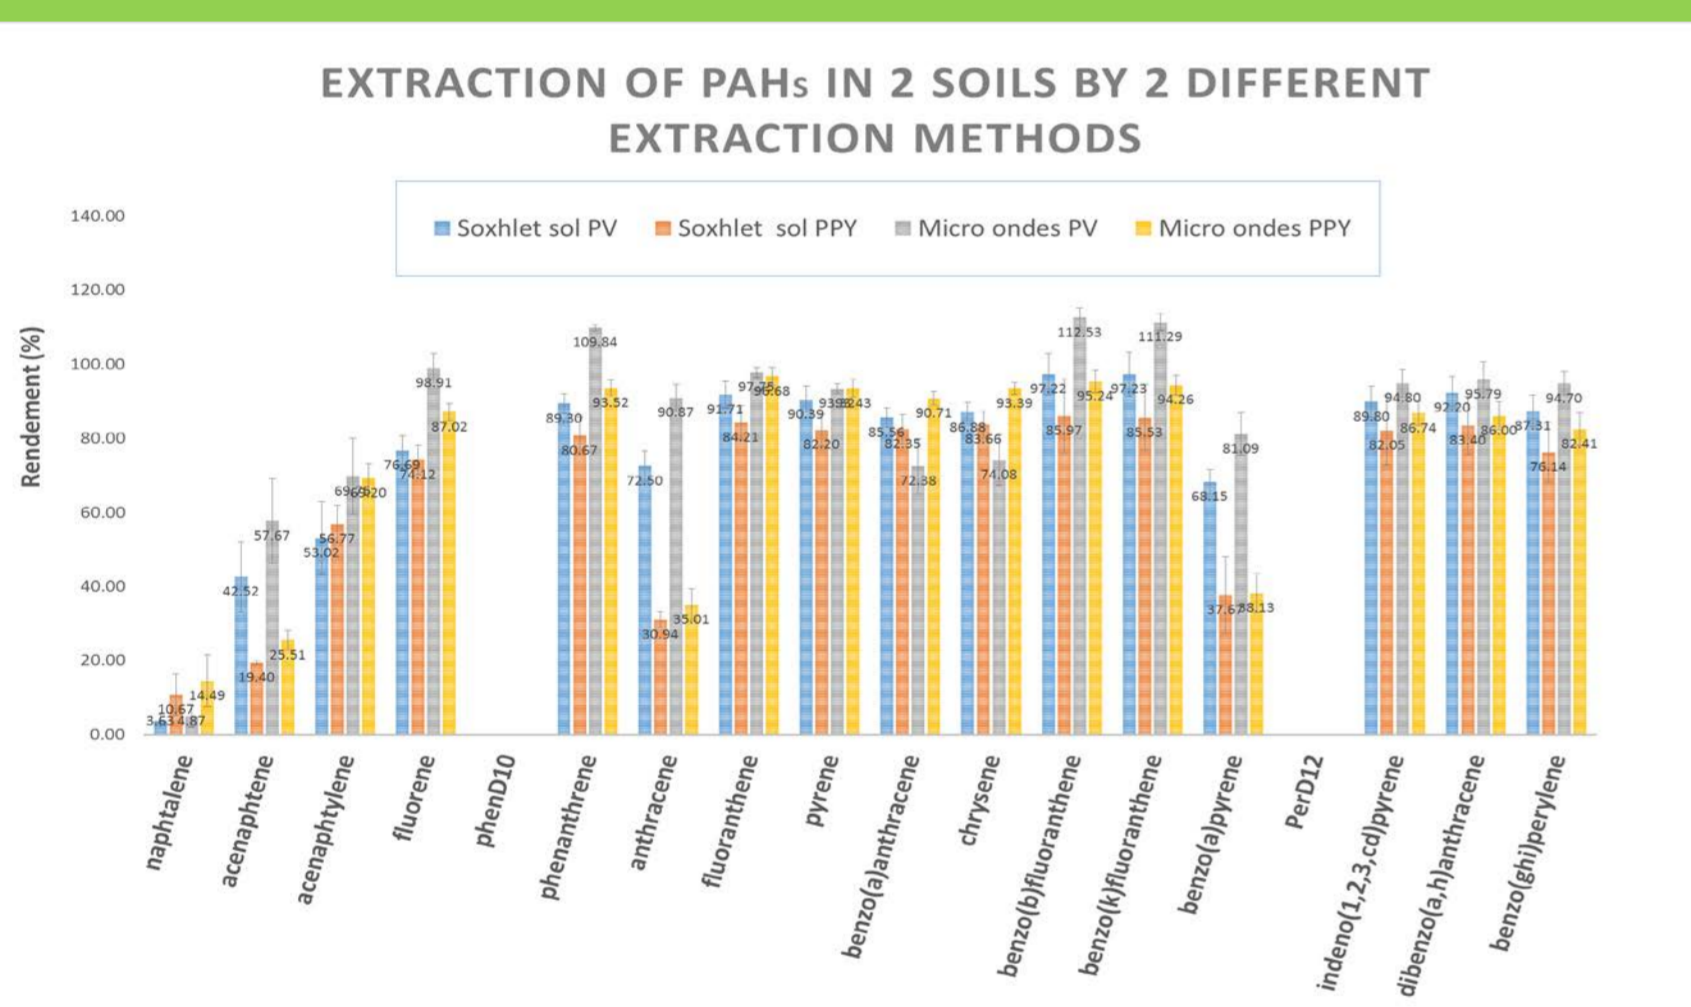

- Acenaphtalene, fluorene and anthracene > N1 GEODE (< N2), other PAHs < N1.
- PCBs < N1.
- Metals < N1, but Cd > N2.

HPLC-UV analysis for PAH quinones

- Hexane/Acetone 50/50: more efficient
- Recovery of PAHs 60% (<71,4% with MAE) and PCBs 90% (>84.5 with MAE).
- Effect of solvent volume and combinations of dispersants = not significant
- MSPD: simpler and faster than MAE

- 4 PAH quinones are separated by C18 RP column.
- Resolution is good enough.
- Problem: UV detection not enough selective (pics may coincide with other substances)

- MAE (microwave) is more efficient and faster than the traditional Soxhlet method.
- Acetone/Toluene or CH₂Cl₂ = good extracting solvents for PAHs+PCBs

Conclusion

- GC-MS and ICP-AES are adapted to detect different pollutant families in sediment.
- Extraction efficiency: MSPD > MAE > Soxhlet.
 - MSPD still needs optimization (necessary to introduce surrogate standards to correct results related to poor reproducibility of flow-rates).
- HPLC-UV not enough selective to analyse PAHs metabolites
 - Coupling UV+fluorescence ? GC-MS after derivatization?

Perspectives

- Improving EK treatments using original additive mixtures: biosurfactants + citric acid
- Detect PAH metabolites (quinones + hydroxyl-) and reduced PCBs after EK treatment => link with sediment toxicity?
- Microcosms tests to monitor natural dissipation of contaminants in Tancarville sediment (comparison with EK treatment efficiency)
